# Appendix A

# Planning

The project was planned in multiple stages ahead of time. Planning only took place for a certain number of topics ahead and for major checkpoints. Later the major plans @were refined further into smaller segments and the plan table, which can be seen below, was also extended with small chunks of log information as to what topics were covered during major meetings. Overall the project and thesis was on a good track until November 2022, when multiple work and school related events caused it to go off track fairly drastically. It wasn't particularly too hard to catch up to the gap, however the submission is still a bit of a close call.

# Appendix B

# User Documentation

## B.1 Setting up webhosting access

First create a database for the project, copy .env.example to .env, disable debug and set the database login details in the given file. In case you're going to utilize the Dockerized version (either by using the provided image or by building one yourself from the Dockerfile) don't change the provided database details. Make sure to upload the file onto your webhosting alongside the whole project.

```
APP_DEBUG=false
...

DB_CONNECTION=mysql

DB_HOST=127.0.0.1

DB_PORT=3306

DB_DATABASE=homestead

DB_USERNAME=homestead

DB_PASSWORD=secret
```

## B.2 Webhosting deployment

The folder hierarchy has to be copied with the exception of .git and node\_modules onto the public part of the webhosting by utilizing SFTP or related technologies. Afterwards a database has to be migrated. This can be done by setting up the .env file as mentioned above and then using the following commands on your machine in the same folder:

php artisan migrate

This way all of the required database tables will be created.

## B.3 Accessing common functionality

The main functionality of the website is available through the search on the navigation pane. This way any user is able to search the database for cats and any matches he may find are displayable as a profile or a tree. Next to the main functionality users can find test mating. With test mating any user can query the database for male and female cats, optionally of the same breed and compare their inbreeding which is calculated on the frontend. Additionally on the unpublished routes, there is a capability to view charts of the cat's family tree and birthdays. User can also register an account, although this won't allow them to register a new cat nor view backups, because each user account has to be flagged as an administrator manually in the database itself.

## B.4 Creating a new user account

A new user account can be created using the *register* route accessible through the main navigation. User is requested to input their e-mail which will be used as the main means of logging in. Additionally the user is requested to input their name and password. The password is hashed on the side of the database.

# B.5 Accessing Backups and Cat Registration functionality

The user can access backups and cat registration if their account is flagged as administrator on the side of the database. This requires someone with database access to manually go into the *users* table and flag the *is\_admin* boolean as true for the given user.

# B.5.1 Setting up an administrator account on a Dockerized build

If you're the administrator, then you will likely wish to create an admin account so you can access cat registration, edit and backup features. In order to do this simply register an account, open the MariaDB console:

To open the console first check which Docker container is yours, then substitute xxxx with your container id:

```
docker container ls

CONTAINER ID IMAGE COMMAND CREATED STATUS PORTS

ad4951b8d9cd bp:2.0 "sh entrypoint.sh --" 51 minutes ago Up 51

→ minutes 127.0.0.1:8000->8000/tcp
```

In the example above Container ID can be clearly seen. This identification will be used to access the containers shell and from there the MariaDB console without having to expose any additional ports:

```
docker container exec -it xxxx /bin/sh mariadb
```

Then after getting to the MariaDB console proceed to use the following list of queries. Substitute yyyy for your user's id from the query on the previous line which shows all users:

```
use homestead;
show tables;
select * from users;
update users set is_admin = TRUE where id = yyyy;
```

Now the user with id *yyyy* became an administrator. You can exit the shell and docker container:

```
exit exit
```

# Appendix C

# Technical Documentation

## C.1 Folder hierarchy

Based on the MVC architecture we can delineate the major folder structure as follows:

- app contains the Models
- app/Http/Controllers contains the Controllers, which within their methods link to Views
- resources/views contain the Views themselves, which get to use Model methods where necessary using the syntax

#### Additionally:

- routes contain the GET, POST and DELETE routes which link to Controller methods
- test contains Functional and Unit tests
- database/migrations contains the migrations necessary for Models to function

## C.2 Dockerfile contents, build and launch order

```
FROM ubuntu: jammy
WORKDIR /app
COPY . /app
ENV DEBIAN_FRONTEND=noninteractive
RUN apt update
RUN apt-get --purge remove php-common
RUN apt install php-common php-mysql php-cli -y
RUN apt install mariadb-server -y
RUN cp -r /app/mariadb.service /etc/systemd/system
RUN service mariadb start && mariadb -u root -e "CREATE DATABASE
   → homestead; GRANT ALL ON *.* TO 'homestead'@'localhost'
   \hookrightarrow IDENTIFIED BY 'secret' WITH GRANT OPTION; FLUSH PRIVILEGES;"
RUN mkdir -p /usr/lib/php/20210902
\chapter{RUN cp -r pdo_mysql.so /usr/lib/php/20210902}
RUN cp -r php.ini /etc/php/8.1/cli
RUN php artisan key:generate
RUN service mariadb start && php artisan migrate
ENTRYPOINT ["sh", "entrypoint.sh"]
```

Firstly a Ubuntu image gets used, then all app data get copied onto the /app folder. Next an adjustment gets made to automate commands without an interactive environment. apt follows up with an installation of all relevant packages:

- php-common
- php-mysql
- php-cli

#### - mariadb-server

Then mariadb gets setup to run on the same image as the main application. Next up an adjustment to the php installation so the maximum upload size is accordingly adjusted. Lastly Laravel key gets generated and MariaDB launched for migrations. All of these steps get done ahead of the runtime of a Docker image in order to build it.

After the Docker image gets built the entrypoint gets called:

```
#!/bin/sh

#ping -t localhost

service mariadb start && php artisan serve --host 0.0.0.0 --port

\hookrightarrow 8000
```

This includes running the mariadb service and web server on the port 8000, which is exposed in the relevant Docker run command:

```
docker build -t bp:2.0 .
docker run -dp 127.0.0.1:8000:8000 bp:2.0 --name bp
```

#### C.2.1 Ports

Only port opened to the host is 8000. In case you need to expose the mariadb as well (which is not necessary as you can access it using docker exec -it followed up with the mariadb command) make sure to expose the port 3306 in the docker run.

#### C.3 APIs and Routes

The following routes have been programmed:

GET:
- /
- home
- profile
- profile-search
- cats/cat
- $\operatorname{cats/cat/chart}$ (disabled in navigation due to performance issues)
- $cats/cat/tree$
- $test/cat/cat2$
- $cats/cat/tree/generations$
- $cats/cat/death$
- birthdays (disabled in navigation on webhosting due to query result length issues)
- $birthdays/month/day$
- register-cat
- $cats/cat/edit$
- backups/help
- backups/fileName/dl
- register
- login
- forgot-password

## Appendix C. Technical Documentation

- logout
POST:
- register-cat
- family-actions/cat/set-sire
- family-actions/cat/set-dam
- family-actions/cat/set-parent
- $\mathrm{cats/cat}$
- backups/issue
- backups/export
- backups/import
- backups/export_breeds
- backups/import_breeds
- backups/export_ems
- backups/import_ems
- backups/upload
$-\ backups/fileName/restore$
- language/change
- register

- login

- forgot-password

## Appendix C. Technical Documentation
